

## Confidence Intervals

### Estimating Means

For large  $r$ ,  $t_r \rightarrow N(0, 1)$  is a good approximation.

#### Normal, Single Mean, Known $\sigma$

$(\bar{x} \pm c \frac{\sigma}{\sqrt{n}})$ ; with  $c = F^{-1}(1 - \frac{\alpha}{2})$  from pivot  $N(0, 1)$ .

#### Normal, Single Mean, Unknown $\sigma$

$(\bar{x} \pm c \frac{s}{\sqrt{n}})$ ; with  $c = F^{-1}(1 - \frac{\alpha}{2})$  from pivot  $t_{n-1}$ .

#### Normal, Two Means, Two Known $\sigma$ 's

$(\bar{x} - \bar{y}) \pm c \sqrt{\frac{\sigma_X^2}{n} + \frac{\sigma_Y^2}{m}}$ ; with  $c$  from pivot  $N(0, 1)$ .

#### Normal, Two Means, Unknown $\sigma$ 's, Many Samples

$(\bar{x} - \bar{y}) \pm c \sqrt{\frac{s_X^2}{n} + \frac{s_Y^2}{m}}$ ; with  $c$  from pivot  $N(0, 1)$ .

#### Normal, Two Means, Unknown $\sigma$ 's, Common Variance

$(\bar{x} - \bar{y}) \pm c \cdot s_P \sqrt{\frac{1}{n} + \frac{1}{m}}$ ; with  $c$  from pivot  $t_{n+m-2}$ .

$$s_P = \sqrt{\frac{(n-1)s_X^2 + (m-1)s_Y^2}{n+m-2}}$$

#### Normal, Two Means, Unknown $\sigma$ 's, $\neq$ Variances

$(\bar{x} - \bar{y}) \pm c \sqrt{\frac{s_X^2}{n} + \frac{s_Y^2}{m}}$ ; with  $c$  from pivot  $t_r$ .

$$r = \left( \frac{s_X^2}{n} + \frac{s_Y^2}{m} \right)^2 / \left( \frac{s_X^4}{n^2(n-1)} + \frac{s_Y^4}{m^2(m-1)} \right)$$

#### Normal, Paired Samples

For pairs  $(X_i, Y_i)$ , let  $D_i = X_i - Y_i$ .  $D_i \sim N(\mu_D, \sigma_D^2)$ .

$(\bar{d} \pm c \frac{s_d}{\sqrt{n}})$ ; with  $c$  from pivot  $t_{n-1}$ .

### Estimating Variance

#### Normal, Single Variance - **estimate of $\sigma^2$ not $\sigma$ !**

$(\frac{(n-1)s^2}{b}, \frac{(n-1)s^2}{a})$ ; with  $a, b$  from pivot  $\chi_{n-1}^2$ .

#### Normal, Two Variances

A confidence interval for the ratio of the variances  $\sigma_X^2/\sigma_Y^2$  is  $(a \cdot \frac{s_X^2}{s_Y^2}, b \cdot \frac{s_X^2}{s_Y^2})$ ; with  $a, b$  from pivot  $F_{m-1, n-1}$ .

### Estimating Proportions (Large n - Normal Approx.)

#### Single Proportion

$\approx (\hat{p} \pm c \sqrt{\frac{\hat{p}(1-\hat{p})}{n}})$ ; with  $c$  from pivot  $N(0, 1)$ .

#### Two Proportions

$\approx (\hat{p}_1 - \hat{p}_2 \pm c \sqrt{\frac{\hat{p}_1(1-\hat{p}_1)}{n_1} + \frac{\hat{p}_2(1-\hat{p}_2)}{n_2}})$ ;  $c$  from pivot  $N(0, 1)$ .

Can also derive a confidence interval from the exact distribution of the binomial RV  $n \cdot \hat{p} \sim \text{Bi}(n, p)$ .

### Prediction Intervals

Let  $X^*$  be a future realisation of  $X$ .

If  $X \sim N(\mu, \sigma^2)$ ,  $\bar{X} \sim N(\mu, \frac{\sigma^2}{n})$ , and  $(\bar{X} - X^*) \sim N(0, \sigma^2 + \frac{\sigma^2}{n})$ .

$(\bar{x} \pm c \sqrt{s^2 + \frac{s^2}{n}})$  is a prediction interval with  $c$  from  $t_{n-1}$ .

If  $\sigma$  is known, use pivot  $N(0, 1)$ . If  $\mu$  is known use  $\chi_{n-1}^2$ .

## Regression

### Ordinary Least Square (OLS) Estimators

All parameters are unbiased and except  $\hat{\sigma}^2$  are normally distributed (Variances as below).

Let  $K = \sum_{i=1}^n (x_i - \bar{x})^2$  and  $D^2 = \sum_{i=1}^n (Y_i - \hat{\alpha}_0 - \hat{\beta}(x_i - \bar{x}))^2$ :

$$\hat{\alpha}_0 = \bar{Y}; \quad \hat{\beta} = \frac{\sum_{i=1}^n (x_i - \bar{x})Y_i}{\sum_{i=1}^n (x_i - \bar{x})^2}; \quad \hat{\alpha} = \hat{\alpha}_0 - \hat{\beta}\bar{x}; \quad \hat{\sigma}^2 = \frac{D^2}{n-2}$$

$$\text{Var}(\hat{\alpha}) = \left( \frac{1}{n} + \frac{\bar{x}^2}{K} \right) \sigma^2; \quad \text{Var}(\hat{\beta}) = \frac{\sigma^2}{K}; \quad \text{Var}(\hat{\alpha}_0) = \frac{\sigma^2}{n}$$

$$\text{Cov}(\hat{\alpha}_0, \hat{\beta}) = 0; \quad \text{Var}(\hat{\mu}(x)) = \left( \frac{1}{n} + \frac{(x - \bar{x})^2}{K} \right) \sigma^2$$

### Regression Pivots

Notice that all the  $t_{n-2}$  distributed pivots are estimate  $\div$  SE.

$$\frac{(n-2)\hat{\sigma}^2}{\sigma^2} \sim \chi_{n-2}^2; \quad \frac{\hat{\beta} - \beta}{\hat{\sigma}/\sqrt{K}} \sim t_{n-2}; \quad \frac{\hat{\mu}(x) - \mu(x)}{\hat{\sigma}\sqrt{\frac{1}{n} + \frac{(x-\bar{x})^2}{K}}} \sim t_{n-2}$$

$$\frac{\hat{\alpha} - \alpha}{\hat{\sigma}\sqrt{\frac{1}{n} + \frac{\bar{x}^2}{K}}} \sim t_{n-2}; \quad \frac{\hat{\alpha}_0 - \alpha_0}{\hat{\sigma}/\sqrt{n}} \sim t_{n-2}$$

## Distribution Free Methods

### Sign Test

**Hypotheses:**  $H_0 : m = m_0$ ;  $H_1 : m \neq m_0$  or 1 sided  $H_1$ .

Let  $Y = \sum_{i=1}^n I(X_i - m_0 > 0)$ . Under  $H_0$ ,  $Y \sim \text{Bi}(n, 0.5)$ . Can calculate  $p$  values or a critical region from  $Y \sim \text{Bi}(n, 0.5)$ .

**Paired Samples:** Replace  $(x_i, y_i)$  with  $\text{sgn}(x_i - y_i)$  and use the same distribution to check for equal medians.

### Wilcoxon Signed Rank / One Sample Test

**Hypotheses:**  $H_0 : m = m_0$ ;  $H_1 : m \neq m_0$  or 1 sided  $H_1$ .

Rank the  $|X_i - m_0|$  from  $1 \rightarrow n$  starting at 1 and replace  $X_i$  with  $\text{sgn}(X_i - m_0) \cdot \text{rank}(|X_i - m_0|)$ . Let  $W$  be the sum of the signed ranks. Under  $H_0$ :

$$Z = \frac{W - 0}{\sqrt{n(n+1)(2n+1)/6}} \approx N(0, 1)$$

For paired samples we can take the difference and test for equality of medians. When tied ranks occur give them each the average of the ranks they span.

### Wilcoxon Rank Sum / Two Sample Test

**Hypotheses:**  $H_0 : m_X = m_Y$ ;  $H_1 : \bar{H}_0$  or 1 sided  $H_1$ .

Order the combined sample and let  $W$  be the sum of the ranks of  $Y_1, \dots, Y_{n_Y}$ .  $W$  is approximately normal with:

$$\mathbb{E}(W) = \frac{n_Y(n_X + n_Y + 1)}{2}; \quad \text{Var}(W) = \frac{n_X n_Y (n_X + n_Y + 1)}{12}$$

## Bayesian Inference

**USE THE LIKELIHOOD NOT THE PDF!**

### Law of Total Probability

$$f(x) = \int_{-\infty}^{\infty} f(x, y) dy = \int_{-\infty}^{\infty} f(x | y) f(y) dy$$

### Normal Distribution, Known $\sigma$ , Inference for $\mu$

$X_1, \dots, X_n \sim N(\mu, \sigma^2)$ . Let  $Y = \bar{X} \sim N(\mu, \sigma^2/n)$ .

Prior:  $\mu \sim N(\mu_0, \sigma_0^2)$

Posterior:  $f(\mu | y) \propto f(y | \mu) f(\mu) \propto \exp \left[ -\frac{(\mu - \mu_1)^2}{2\sigma_1^2} \right]$

Where:

$$\mu_1 = \frac{\frac{\mu_0}{\sigma_0^2} + \frac{y}{\sigma^2/n}}{\frac{1}{\sigma_0^2} + \frac{1}{\sigma^2/n}}; \quad \frac{1}{\sigma_1^2} = \frac{1}{\sigma_0^2} + \frac{1}{\sigma^2/n}$$

So  $\mu | y \sim N(\mu_1, \sigma_1^2)$

### Binomial Distribution, Beta / Uniform Prior

$X \sim \text{Bi}(n, \theta)$ . Prior:  $\theta \sim \text{Beta}(\alpha, \beta)$

Posterior:  $\theta | x \sim \text{Beta}(\alpha + x, \beta + n - x)$

### Pseudodata

Gamma prior:  $\gamma(\alpha, \beta)$  where  $\alpha$  is the total count over all samples and  $\beta$  is the number of samples taken.

Beta prior:  $\text{Beta}(\alpha, \beta)$  where  $\alpha$  is the number of successes and  $\beta$  is the number of failures.

## Pivots

Sampling from a normal distribution:

$$\frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \sim N(0, 1); \quad \frac{\bar{X} - \mu}{s/\sqrt{n}} \sim t_{n-1}; \quad \frac{(n-1)S^2}{\sigma^2} \sim \chi_{n-1}^2$$

**ANOVA**

All populations assumed to have equal variance.

**F-Statistics / F-test**

To test any  $H_0$  in ANOVA, use the F statistic. Since the  $MS$  terms are  $\chi^2$  distributed,  $F = MS(X) \div MS(E)$  is distributed as  $F_{df_X, df_E}$  and the rejection region is  $F > c$ .

eg. To test  $H_{0AB} : \gamma_{ij} = 0 \forall i, j$  use  $F_{(a-1)(b-1), ab(c-1)}$ .

**Single Factor (One Way) ANOVA**

Total Sample Size:  $n = n_1 + \dots + n_k$

**Means:**

$$\bar{X}_{i.} = \frac{1}{n_i} \sum_{j=1}^{n_i} X_{ij}; \quad \bar{X}_{..} = \frac{1}{n} \sum_{i=1}^k \sum_{j=1}^{n_i} X_{ij} = \frac{1}{n} \sum_{i=1}^k n_i \bar{X}_{i.}$$

**Hypotheses:**  $H_0 : \mu_1 = \mu_2 = \dots = \mu_k$  vs.  $H_1 : \bar{H}_0$

**Sum of Squares:**

Treatment SS:

$$SS(T) = \sum_{i=1}^k \sum_{j=1}^{n_i} (\bar{X}_{i.} - \bar{X}_{..})^2 = \sum_{i=1}^k n_i (\bar{X}_{i.} - \bar{X}_{..})^2$$

Error SS:

$$SS(E) = \sum_{i=1}^k \sum_{j=1}^{n_i} (X_{ij} - \bar{X}_{i.})^2 = \sum_{i=1}^k (n_i - 1) S_i^2$$

Total SS:

$$SS(TO) = \sum_{i=1}^k \sum_{j=1}^{n_i} (X_{ij} - \bar{X}_{..})^2 = SS(T) + SS(E)$$

**Degrees of Freedom:**

$$\text{Treatment : } k - 1; \quad \text{Error : } n - k$$

**Null Distributions of Sum of Squares Terms:**

$$\frac{SS(T)}{\sigma^2} \sim \chi_{k-1}^2; \quad \frac{SS(E)}{\sigma^2} \sim \chi_{n-k}^2; \quad \frac{SS(TO)}{\sigma^2} \sim \chi_{n-1}^2$$

**Two Factor (Two Way) ANOVA**

Assume  $X_{ij} \sim N(\mu_{ij}, \sigma^2)$ .  $\mu_{ij} = \mu + \alpha_i + \beta_j$ .  $\sum_{i=1}^a \alpha_i = 0$  and  $\sum_{j=1}^b \beta_j = 0$ . Take one observation from each combination of  $a$  and  $b$  ( $n = ab$ ).

**Hypotheses:**  $H_{0A} : \alpha_1 = \alpha_2 = \dots = \alpha_k = 0$  vs.  $H_1 : \bar{H}_0$

or  $H_{0B} : \beta_1 = \beta_2 = \dots = \beta_k = 0$  vs.  $H_1 : \bar{H}_0$

**Means:**

$$\bar{X}_{..} = \frac{1}{ab} \sum_{i=1}^a \sum_{j=1}^b X_{ij}; \quad \bar{X}_{i.} = \frac{1}{b} \sum_{j=1}^b X_{ij}; \quad \bar{X}_{.j} = \frac{1}{a} \sum_{i=1}^a X_{ij}$$

**Sum of Squares:**

$$SS(A) = b \sum_{i=1}^a (\bar{X}_{i.} - \bar{X}_{..})^2$$

$$SS(B) = a \sum_{j=1}^b (\bar{X}_{.j} - \bar{X}_{..})^2$$

Error SS:

$$SS(E) = \sum_{i=1}^a \sum_{j=1}^b (X_{ij} - \bar{X}_{i.} - \bar{X}_{.j} + \bar{X}_{..})^2$$

Total SS:

$$SS(TO) = SS(A) + SS(B) + SS(E)$$

**Degrees of Freedom:**

$$A : a - 1; \quad B : b - 1; \quad \text{Error : } (a - 1)(b - 1)$$

**Two Factor ANOVA with Interaction Terms**

Take samples over two factors, but  $c$  samples for each factor pair.  $\mu_{ij} = \mu + \alpha_i + \beta_j + \gamma_{ij}$ .

**Hypotheses:**  $H_{0A} : \alpha_1 = \alpha_2 = \dots = \alpha_k = 0$  vs.  $H_1 : \bar{H}_0$

or  $H_{0B} : \beta_1 = \beta_2 = \dots = \beta_k = 0$  vs.  $H_1 : \bar{H}_0$

or  $H_{0AB} : \gamma_{ij} = 0 \forall i, j$  vs.  $H_1 : \bar{H}_0$

**Means:**

$$\bar{X}_{ij.} = \frac{1}{c} \sum_{k=1}^c X_{ijk}; \quad \bar{X}_{i..} = \frac{1}{bc} \sum_{j=1}^b \sum_{k=1}^c X_{ijk}$$

$$\bar{X}_{.j.} = \frac{1}{ac} \sum_{i=1}^a \sum_{k=1}^c X_{ijk}; \quad \bar{X}_{...} = \frac{1}{abc} \sum_{i=1}^a \sum_{j=1}^b \sum_{k=1}^c X_{ijk}$$

**Sum of Squares:**

$$SS(A) = bc \sum_{i=1}^a (\bar{X}_{i..} - \bar{X}_{...})^2$$

$$SS(B) = ac \sum_{j=1}^b (\bar{X}_{.j.} - \bar{X}_{...})^2$$

$$SS(AB) = c \sum_{i=1}^a \sum_{j=1}^b (\bar{X}_{ij.} - \bar{X}_{i..} - \bar{X}_{.j.} + \bar{X}_{...})^2$$

Error SS:

$$SS(E) = \sum_{i=1}^a \sum_{j=1}^b \sum_{k=1}^c (X_{ijk} - \bar{X}_{ij.})^2$$

Total SS:

$$SS(TO) = SS(A) + SS(B) + SS(AB) + SS(E)$$

**Degrees of Freedom:**

$$A : a - 1; \quad B : b - 1; \quad AB : (a - 1)(b - 1); \quad \text{Error : } ab(c - 1)$$

**Mean Squares / Mean Square Error**

MSE is found by dividing the  $SS(E)$  by its degrees of freedom.

$\hat{\sigma}^2 = MS(E)$  is an unbiased estimator for the variance.

**Distribution of Quantiles and Order Statistics**

**CDF of  $X_{(k)}$**

$$G_k(x) = \Pr(X_k \leq x) = \sum_{i=k}^n \binom{n}{i} F(x)^i (1 - F(x))^{n-i}$$

**PDF of  $X_{(k)}$**

$$g_k(x) = k \binom{n}{k} F(x)^{k-1} (1 - F(x))^{n-k} f(x)$$

**Asymptotic Distribution of  $\hat{\pi}_p$**

$$\hat{\pi}_p \approx N\left(\pi_p, \frac{p(1-p)}{n \cdot f(\pi_p)^2}\right); \quad \hat{M} \approx N\left(m, \frac{1}{4n \cdot f(m)^2}\right)$$

**Goodness-of-fit Test ( $\chi^2$ )**

$O_i$  is the Observed count of data in class  $i$ ,  $E_i$  ( $> 5$ ) is the Expected count under  $H_0$ . Be careful to use the count and not the proportion. For  $k$  classes and  $e$  estimated parameters:

$$Q_{k-1-e} = \sum_{i=1}^k \frac{(O_i - E_i)^2}{E_i} \approx \chi_{k-1-e}^2$$

Since the numerator  $(O_i - E_i)^2$  will be larger when  $H_0$  is false, we reject  $H_0$  for  $Q_{k-1-e} > c$ , with  $c$  from  $\chi_{k-1-e}^2$ .

**Two Classes ( $k = 2$ )**

Testing  $H_0 : p = p_1$  vs.  $H_1 : p \neq p_1$

**More than Two Classes ( $k > 2$ )**

Let  $p_1, \dots, p_k$  define the proportions of a categorical distribution.  $H_0 : "p_1, \dots, p_k \text{ do define the distribution}"$  vs.  $H_1 : \bar{H}_0$

**Sufficient Statistics**

**Exponential Family**

$$f(x | \theta) = \exp\{K(x)p(\theta) + S(x) + q(\theta)\}$$

Has  $\sum_{i=1}^n K(X_i)$  as a sufficient statistic for  $\theta$ .

**Factorisation Theorem**

$Y = g(x_1, \dots, x_n)$  is sufficient for  $\theta$  iff:

$$f(x_1, \dots, x_n | \theta) = \phi\{g(x_1, \dots, x_n) | \theta\} h(x_1, \dots, x_n)$$

**Other Formulae**

**Sample Variance**

$$s^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2 = \frac{1}{n-1} ((\sum_{i=1}^n x_i^2) - n\bar{x}^2)$$

**Cramér-Rao Lower Bound**

The CR Lower Bound is the minimum possible variance of an estimator  $\hat{\theta}$  of  $\theta$ . It is the asymptotic variance of the MLE.

$$\ell(\theta) = \ln L(\theta); \quad U(\theta) = \frac{\partial \ell}{\partial \theta} \quad (\text{Score Function})$$

$$V(\theta) = -\frac{\partial U}{\partial \theta}; \quad I(\theta) = \mathbb{E}(V(\theta)) \quad (\text{Fisher Information})$$

$$\text{Var}(\hat{\theta}) \geq \frac{1}{I(\theta)} \quad (\text{CR Lower Bound})$$

In the Fisher Information, take  $\mathbb{E}(V(\theta))$  over all  $x$ , not  $\theta$ .

**Gamma Function in Beta +  $\gamma$  Distributions**

$$\Gamma(n) = (n-1)!$$
